

Experiment No - 3

Aim: Implement following Programs Using Lex

- a. Convert Roman to Decimal
- b. Check weather given statement is compound or simple
- c. Extract html tags from .html file

Date: // Write date of experiment here

Competency and Practical Skills: Understanding of Lex tool and its usage in compiler design, understanding of regular expressions and data structures, improving programming skill to develop programs using lex tool

Relevant CO: CO1

Objectives:

1. To introduce students to Lex tool and its usage in compiler design
2. To provide practical knowledge of regular expressions and their use in pattern matching
3. To enhance students' understanding of data structures such as arrays, lists, and trees
4. To develop students' problem-solving skills in developing and implementing programs using Lex tool
5. To develop students' debugging skills to identify and resolve program errors and issues

Software/Equipment: Computer system, Text editor, Lex tool, C compiler, Terminal or Command prompt.

Theory:

❖ **LEX:**

- Lex is a program that generates lexical analyzers. It is used with a YACC parser generator.
- The lexical analyzer is a program that transforms an input stream into a sequence of tokens.
- It reads the input stream and produces the source code as output through implementing the lexical analyzer in the C program.
- During the first phase the compiler reads the input and converts strings in the source to tokens.
- With regular expressions we can specify patterns to lex so it can generate code that will allow it to scan and match strings in the input. Each pattern specified in the input to lex has an associated action.
- Typically an action returns a token that represents the matched string for subsequent use by the parser. Initially we will simply print the matched string rather than return a token value.

➤ **Function of LEX:**

- Firstly lexical analyzer creates a program lex.l in the Lex language. Then Lex compiler runs the lex.l program and produces a C program lex.yy.c.
- Finally C compiler runs the lex.yy.c program and produces an object program a.out.
- a.out is a lexical analyzer that transforms an input stream into a sequence of tokens.

➤ **LEX File Format:**

- A Lex program is separated into three sections by %% delimiters. The format of Lex source is as follows:
% { definitions % }
%%
{ rules }
%%
{ user subroutines }
• Definitions include declarations of constant, variable and regular definitions.

- Rules define the statement of form $p_1 \{action_1\} p_2 \{action_2\} \dots p_n \{action_n\}$.
- Where p_i describes the regular expression and $action_i$ describes the actions the lexical analyzer should take when pattern p_i matches a lexeme.
- User subroutines are auxiliary procedures needed by the actions. The subroutine can be loaded with the lexical analyzer and compiled separately.

❖ FLEX: Fast Lexical Analyzer Generator

- FLEX is a tool/computer program for generating lexical analyzers (scanners or lexers) written by Vern Paxson in C around 1987. It is used together with Berkeley Yacc parser generator or GNU Bison parser generator. Flex and Bison both are more flexible than Lex and Yacc and produce faster code.
- Bison produces parsers from the input file provided by the user. The function `yylex()` is automatically generated by the flex when it is provided with a `.l` file and this `yylex()` function is expected by parser to call to retrieve tokens from current/this token stream.

STEPS:

- Step 1 : An input file describes the lexical analyzer to be generated named `lex.l` is written in lex language. The lex compiler transforms `lex.l` to C program, in a file that is always named `lex.yy.c`.
- Step 2 : The C compiler compile `lex.yy.c` file into an executable file called `a.out`.
- Step 3 : The output file `a.out` take a stream of input characters and produce a stream of tokens.
- Program Structure:

In the input file, there are 3 sections:

Definition Section: The definition section contains the declaration of variables, regular definitions, and manifest constants. In the definition section, text is enclosed in “`%{ %}`” brackets. Anything written in this brackets is copied directly to the file `lex.yy.c`

Syntax:

```
%{
// Definitions
%}
```

Rules Section: The rules section contains a series of rules in the form: pattern action and pattern must be unintended and action begin on the same line in `{ }` brackets. The rule section is enclosed in “`%% %%%`”.

Syntax:

```
%%
pattern action
%%
```

User Code Section: This section contains C statements and additional functions. We can also compile these functions separately and load with the lexical analyzer.

How to run the program:

To run the program, it should be first saved with the extension `.l` or `.lex`. Run the below commands on terminal in order to run the program file.

- Step 1: `lex filename.l` or `lex filename.lex` depending on the extension file is saved with name.l extension.
- Step 2: `gcc lex.yy.c`
- Step 3: `./a.out`
- Step 4: Provide the input to program in case it is required

Program:***Program-1: Convert Roman to Decimal***

Code:

```
% {
#include <stdio.h>

int decimal = 0; // to store the decimal value
int prev_value = 0; // to store the value of the previous Roman numeral
% }

/* Rules section */
%%
I      { prev_value = 1; } // If the symbol is 'I', set prev_value to 1
IV     { decimal += 3; }  // If the symbol is 'IV', add 3 to the decimal value
V      { decimal += 5; }  // If the symbol is 'V', add 5 to the decimal value
IX     { decimal += 8; }  // If the symbol is 'IX', add 8 to the decimal value
X      { decimal += 10; } // If the symbol is 'X', add 10 to the decimal value
XL     { decimal += 30; } // If the symbol is 'XL', add 30 to the decimal value
L      { decimal += 50; } // If the symbol is 'L', add 50 to the decimal value
XC     { decimal += 80; } // If the symbol is 'XC', add 80 to the decimal value
C      { decimal += 100; } // If the symbol is 'C', add 100 to the decimal value
CD     { decimal += 300; } // If the symbol is 'CD', add 300 to the decimal value
D      { decimal += 500; } // If the symbol is 'D', add 500 to the decimal value
CM     { decimal += 800; } // If the symbol is 'CM', add 800 to the decimal value
M      { decimal += 1000; } // If the symbol is 'M', add 1000 to the decimal value
.      { printf("Invalid Roman numeral\n"); exit(1); } // If any other symbol is encountered, exit
with an error message
%%

/* Code section */
int main()
{
    yylex();
    printf("Decimal value: %d\n", decimal);
    return 0;
}
```

Program-2: Check weather given statement is compound or simple

Code:

*// Write your code here****Program-3: Extract html tags from .html file***

Code:

// Write your code here

Observations and Conclusion:**Program-1:**

```
$ echo "XXI" | lex roman.l && gcc lex.yy.c && ./a.out  
Decimal value: 21
```

The Lex program scans the input Roman numeral and converts it into decimal by matching each symbol with the corresponding decimal value. If an invalid symbol is encountered, the program exits with an error message. Lex provides an efficient and easy way to define the rules for the conversion.

Program-2:

// Write your output and conclusion here as given in program-1

Program-3:

// Write your output and conclusion here as given in program-1

Quiz:

1. What is Lex tool?
2. What is the purpose of Lex tool?
3. What is the aim of the Roman to Decimal conversion program?
4. How does the program check whether a given statement is compound or simple?
5. What is the purpose of the program to extract HTML tags from an HTML file?
6. Explain the Rule Section of a Lex program.
7. What is the purpose of the Definition Section in a Lex program?
8. How can you declare and initialize a variable in a Lex program?
9. How can you compile and execute a Lex program?
